A tour of the Haskell Prelude
1 Haskell

The Haskell language was conceived during a meeting held at the 1987 Functional Programming and Computer Architecture conference (FPCA 87). At the time of the conference it was believed that the advancement of functional programming was being stifled by the wide variety of languages available. There were more than a dozen lazy, purely functional languages in existence and none had widespread support (except perhaps Miranda*). A committee was formed to design the language. The name Haskell was chosen in honour of the mathematician Haskell Curry, whose research forms part of the theoretical basis upon which many functional languages are implemented. Haskell is widely used within the functional programming community, and there exists a number of implementations. In 1998 the Haskell community agreed upon a standard definition of the language and supporting libraries. One of the aims of standardisation was to encourage the creation of text books and courses devoted to the language. The resulting language definition is called Haskell 98.

Haskell is a lazy functional language with polymorphic higher-order functions, algebraic data types and list comprehensions. It has an extensive module system, and supports ad-hoc polymorphism (via classes). Haskell is purely functional, even for I/O. Most Haskell implementations come with a number of libraries supporting arrays, complex numbers, infinite precision integers, operating system interaction, concurrency and mutable data structures. There is a popular interpreter (called Hugs) and many compilers. More information about the Haskell language can be found on following the web-page: www.haskell.org.

The following chapter serves as a reference guide to the Haskell language (specifically Haskell 98). In particular it concentrates on the content of the Haskell Prelude, which is a standard library accessible by all Haskell programs. The chapter does not give complete coverage to the whole Prelude, but instead concentrates on those aspects most useful to Haskell beginners (however it should serve as a valuable resource to experienced Haskell programmers as well). The first part of the chapter deals with Prelude functions, the second part of the chapter deals with Prelude operators, and the third part of the deals with Prelude classes.

---

1.1 Selected Functions from the Haskell Prelude

abs

type: \[ \text{abs} :: \text{Num} \ a => \ a \to \ a \]
description: returns the absolute value of a number.
definition: \[
\text{abs} \ x \\
| x \geq 0 = x \\
| \text{otherwise} = -x
\]
usage: \[
Prelude> \text{abs} \ (-3)
3
\]

all

type: \[ \text{all} :: (a \to \text{Bool}) \to [a] \to \text{Bool} \]
description: applied to a predicate and a list, returns True if all elements of the list satisfy the predicate, and False otherwise. Similar to the function any.
definition: \[ \text{all} \ p \ xs = \text{and} \ (\text{map} \ p \ xs) \]
usage: \[
Prelude> \text{all} \ (<11) \ [1..10]
True
Prelude> \text{all} \ \text{isDigit} \ "123abc"
False
\]

and

type: \[ \text{and} :: [\text{Bool}] \to \text{Bool} \]
description: takes the logical conjunction of a list of boolean values (see also ‘or’).
definition: \[ \text{and} \ xs = \text{foldr} \ (\&\&) \ True \ xs \]
usage: \[
Prelude> \text{and} \ [\text{True}, \text{True}, \text{False}, \text{True}]
False
Prelude> \text{and} \ [\text{True}, \text{True}, \text{True}, \text{True}]
True
Prelude> \text{and} \ []
True
\]

any

type: \[ \text{any} :: (a \to \text{Bool}) \to [a] \to \text{Bool} \]
description: applied to a predicate and a list, returns True if any of the elements of the list satisfy the predicate, and False otherwise. Similar to the function all.
definition: \[ \text{any} \ p \ xs = \text{or} \ (\text{map} \ p \ xs) \]
usage: \[
Prelude> \text{any} \ (<11) \ [1..10]
True
Prelude> \text{any} \ \text{isDigit} \ "123abc"
True
Prelude> \text{any} \ \text{isDigit} \ "alphabetics"
False
\]
atan

type: \( \text{atan} :: \text{Floating a} \Rightarrow a \rightarrow a \)
description: the trigonometric function inverse tan.
definition: defined internally.
usage: Prelude> atan pi
1.26263

break

type: \( \text{break} :: (a \rightarrow \text{Bool}) \rightarrow [a] \rightarrow ([a],[a]) \)
description: given a predicate and a list, breaks the list into two lists (returned as a tuple) at the point where the predicate is first satisfied. If the predicate is never satisfied then the first element of the resulting tuple is the entire list and the second element is the empty list (\([\ ]\)).
definition: \( \text{break} \ p \ xs = \text{span} \ p' \ xs \)  
  where
  \( p' \ x = \text{not} (p \ x) \)
usage: Prelude> break isSpace "hello there fred"
("hello", " there fred")
Prelude> break isDigit "no digits here"
("no digits here","")

ceiling

type: \( \text{ceiling} :: (\text{RealFrac a}, \text{Integral b}) \Rightarrow a \rightarrow b \)
description: returns the smallest integer not less than its argument.
usage: Prelude> ceiling 3.8
4
Prelude> ceiling (-3.8)
-3
note: the function \text{floor} has a related use to \text{ceiling}.

chr

type: \( \text{chr} :: \text{Int} \rightarrow \text{Char} \)
description: applied to an integer in the range \( 0 \rightarrow 255 \), returns the character whose ascii code is that integer. It is the converse of the function \text{ord}. An error will result if \text{chr} is applied to an integer outside the correct range. (Import from \text{Data.Char})
definition: defined internally.
usage: Prelude> chr 65
'A'
Prelude> (ord (chr 65)) == 65
True
**compare**

**type:**
\[
\text{compare :: Ord } a \Rightarrow a \rightarrow a \rightarrow \text{Ordering}
\]

**description:**
applied to two values of the same type which have an ordering defined on them, returns a value of type \text{Ordering} which will be: EQ if the two values are equal; GT if the first value is strictly greater than the second; and LT if the first value is less than or equal to the second value.

**simple definition:**
\[
\text{compare } x \ y
\begin{align*}
| & x == y = \text{EQ} \\
| & x <= y = \text{LT} \\
| & \text{otherwise} = \text{GT}
\end{align*}
\]

**usage:**
Prelude> compare "aadvark" "zebra"
LT

**concat**

**type:**
\[
\text{concat :: } [\text{[a]}] \rightarrow [\text{a}]
\]

**description:**
applied to a list of lists, joins them together using the ++ operator.

**definition:**
\[
\text{concat xs = foldr} \ (++) \ [] \ xs
\]

**usage:**
Prelude> concat [[1,2,3], [4], [], [5,6,7,8]]
[1, 2, 3, 4, 5, 6, 7, 8]

**concatMap**

**type:**
\[
\text{concatMap :: } (a \rightarrow [\text{b}]) \rightarrow [\text{a}] \rightarrow [\text{b}]
\]

**description:**
given a function which maps a value to a list, and a list of elements of the same type as the value, applies the function to the list and then concatenates the result (thus flattening the resulting list).

**definition:**
\[
\text{concatMap } f = \text{concat} \ . \ \text{map} \ f
\]

**usage:**
Prelude> concatMap show [1,2,3,4]
"1234"

**const**

**type:**
\[
\text{const :: } a \rightarrow b \rightarrow a
\]

**description:**
creates a constant valued function which always has the value of its first argument, regardless of the value of its second argument.

**definition:**
\[
\text{const } k \_ = k
\]

**usage:**
Prelude> const 12 "lucky"
12
**cos**

type: \( \text{cos} :: \text{Floating} \ a \Rightarrow a \rightarrow a \)

description: the trigonometric cosine function, arguments are interpreted to be in radians.

definition: defined internally.

usage: 
```haskell
Prelude> \text{cos} \ \pi
-1.0

Prelude> \text{cos} \ (\pi/2)
-4.37114e-08
```

**digitToInt**

type: \( \text{digitToInt} :: \text{Char} \rightarrow \text{Int} \)

description: converts a digit character into the corresponding integer value of the digit. (Import from Data.Char)

definition: \( \text{digitToInt} :: \text{Char} \rightarrow \text{Int} \)

```haskell
digitToInt c
| \text{isdigit} c = \text{fromEnum} c - \text{fromEnum} '0'
| c \geq 'a' \&\& c \leq 'f' = \text{fromEnum} c - \text{fromEnum} 'a' + 10
| c \geq 'A' \&\& c \leq 'F' = \text{fromEnum} c - \text{fromEnum} 'A' + 10
| \text{otherwise} = \text{error} "Char.digitToInt: not a digit"
```

usage: 
```haskell
Prelude> \text{digitToInt} \ '3'
3
```

**div**

type: \( \text{div} :: \text{Integral} \ a \Rightarrow a \rightarrow a \rightarrow a \)

description: computes the integer division of its integral arguments.

definition: defined internally.

usage: 
```haskell
Prelude> 16 \ 'div' \ 9
1
```

**drop**

type: \( \text{drop} :: \text{Int} \rightarrow [a] \rightarrow [a] \)

description: applied to a number and a list, returns the list with the specified number of elements removed from the front of the list. If the list has less than the required number of elements then it returns [].

definition: 
```haskell
drop 0 xs = xs
drop _ [] = []
drop n (\_\:xs) | n\geq0 = drop (n-1) xs
drop _ _ = \text{error} "PreludeList.drop: negative argument"
```

usage: 
```haskell
Prelude> \text{drop} 3 [1..10]
[4, 5, 6, 7, 8, 9, 10]
Prelude> \text{drop} 4 "abc"
""
```
**dropWhile**

type: \[\text{dropWhile} :: (a \rightarrow \text{Bool}) \rightarrow [a] \rightarrow [a]\]
description: applied to a predicate and a list, removes elements from the front of the list while the predicate is satisfied.
definition: \[
dropWhile p \emptyset = \emptyset
\]
\[
dropWhile p (x:xs) = \begin{cases} 
  \text{dropWhile} p \; x = \text{dropWhile} p \; x \; \text{xs} \\
  \text{otherwise} = (x:xs)
\end{cases}
\]
usage: \[
Prelude> \text{dropWhile} (<5) [1..10]
[5, 6, 7, 8, 9, 10]
\]

**elem**

type: \[\text{elem} :: \text{Eq} \; a \Rightarrow a \rightarrow [a] \rightarrow \text{Bool}\]
description: applied to a value and a list returns True if the value is in the list and False otherwise. The elements of the list must be of the same type as the value.
definition: \[
\text{elem} \; x \; xs = \text{any} \; (== \; x) \; xs
\]
usage: \[
Prelude> \text{elem} \; 5 \; [1..10]
\text{True}
\]
\[
Prelude> \text{elem} \; "\text{rat}" \; ["\text{fat}", \; "\text{cat}", \; "\text{sat}", \; "\text{flat}"]
\text{False}
\]

**error**

type: \[\text{error} :: \text{String} \rightarrow a\]
description: applied to a string creates an error value with an associated message. Error values are equivalent to the undefined value (undefined), any attempt to access the value causes the program to terminate and print the string as a diagnostic.
definition: defined internally.
usage: \[
\text{error} \; "\text{this is an error message}"
\]

**even**

type: \[\text{even} :: \text{Integral} \; a \Rightarrow a \rightarrow \text{Bool}\]
description: applied to an integral argument, returns True if the argument is even, and False otherwise.
definition: \[
\text{even} \; n = n \; \text{`rem`} \; 2 \; == \; 0
\]
usage: \[
Prelude> \text{even} \; 2
\text{True}
\]
\[
Prelude> \text{even} \; (\text{11 \times 3})
\text{False}
\]
exp
  type: exp :: Floating a => a -> a
  description: the exponential function (exp n is equivalent to e^n).
  definition: defined internally.
  usage: Prelude> exp 1
           2.71828

filter
  type: filter :: (a -> Bool) -> [a] -> [a]
  description: applied to a predicate and a list, returns a list containing all 
               the elements from the argument list that satisfy the predicate.
  definition: filter p xs = [k | k <- xs, p k]
  usage: Prelude> filter isDigit "fat123cat456"
           "123456"

flip
  type: flip :: (a -> b -> c) -> b -> a -> c
  description: applied to a binary function, returns the same function with 
               the order of the arguments reversed.
  definition: flip f x y = f y x
  usage: Prelude> flip elem [1..10] 5
          True

floor
  type: floor :: (RealFrac a, Integral b) => a -> b
  description: returns the largest integer not greater than its argument.
  usage: Prelude> floor 3.8
          3
Prelude> floor (-3.8)
          -4
  note: the function ceiling has a related use to floor.

foldl
  type: foldl :: (a -> b -> a) -> a -> [b] -> a
  description: folds up a list, using a given binary operator and a given start 
               value, in a left associative manner.
  definition: foldl f z [] = z
              foldl f z (x:xs) = foldl f (f z x) xs
  usage: Prelude> foldl (+) 0 [1..10]
          55
Prelude> foldl (flip (:)) [] [1..10]
          [10, 9, 8, 7, 6, 5, 4, 3, 2, 1]
foldl1

- **type:** foldl1 :: (a -> a -> a) -> [a] -> a
- **description:** folds left over non-empty lists.
- **definition:** foldl1 f (x:xs) = foldl f x xs
- **usage:** Prelude> foldl1 max [1, 10, 5, 2, -1]
  10

foldr

- **type:** foldr :: (a -> b -> b) -> b -> [a] -> b
- **description:** folds up a list, using a given binary operator and a given start value, in a right associative manner.
  foldr op r [a, b, c] → a ‘op’ (b ‘op’ (c ‘op’ r))
- **definition:** foldr f z [] = z
  foldr f z (x:xs) = f x (foldr f z xs)
- **usage:** Prelude> foldr (++) [] ["con", "cat", "en", "ate"]
  "concatenate"

foldr1

- **type:** foldr1 :: (a -> a -> a) -> [a] -> a
- **description:** folds right over non-empty lists.
- **definition:** foldr1 f [x] = x
  foldr1 f (x:xs) = f x (foldr1 f xs)
- **usage:** Prelude> foldr1 (*) [1..10]
  3628800

fromIntegral

- **type:** fromIntegral :: (Integral a, Num b) => a -> b
- **description:** Converts from an Int or Integer to a numeric type which is in the class Num.
- **usage:** Prelude> (fromIntegral 10000000000)::Float
  1.0e+10

fst

- **type:** fst :: (a, b) -> a
- **description:** returns the first element of a two element tuple.
- **definition:** fst (x, _) = x
- **usage:** Prelude> fst ("harry", 3)
  "harry"
**gcd**

**type:** \( \text{gcd} :: \text{Integral } a \Rightarrow a \rightarrow a \rightarrow a \)  

**description:** returns the greatest common divisor between its two integral arguments.

**definition:**

\[
gcd\ 0\ 0 = \text{error} \ "\text{Prelude.gcd: gcd 0 0 is undefined}" \\
gcd\ x\ y = \text{gcd'} \ (\text{abs } x) \ (\text{abs } y) \\
\text{where} \\
gcd' \ x\ 0 = x \\
gcd' \ x\ y = \text{gcd'} \ y \ (x \ \text{`rem' } y)
\]

**usage:**

Prelude> gcd 2 10  
2  
Prelude> gcd (-7) 13  
1

**head**

**type:** \( \text{head} :: [a] \rightarrow a \)  

**description:** returns the first element of a non–empty list. If applied to an empty list an error results.

**definition:**

\[
\text{head} \ (x:_) = x
\]

**usage:**

Prelude> head [1..10]  
1  
Prelude> head ["this", "and", "that"]  
"this"

**id**

**type:** \( \text{id} :: a \rightarrow a \)  

**description:** the identity function, returns the value of its argument.

**definition:**  
\[
\text{id} \ x = x
\]

**usage:**

Prelude> id 12  
12  
Prelude> id (id "fred")  
"fred"  
Prelude> (map id [1..10]) == [1..10]  
True

**init**

**type:** \( \text{init} :: [a] \rightarrow [a] \)  

**description:** returns all but the last element of its argument list. The argument list must have at least one element. If \( \text{init} \) is applied to an empty list an error occurs.

**definition:**

\[
\text{init} \ [x] = [] \\
\text{init} \ (x:xs) = x : \text{init} \ xs
\]

**usage:**

Prelude> init [1..10]  
[1, 2, 3, 4, 5, 6, 7, 8, 9]
isAlpha

**type:**

isAlpha :: Char -> Bool

**description:**
applied to a character argument, returns True if the character is alphabetic, and False otherwise. (Import from Data.Char)

**definition:**

isAlpha c = isUpper c || isLower c

**usage:**

Prelude> isAlpha 'a'
True
Prelude> isAlpha '1'
False

isDigit

**type:**

isDigit :: Char -> Bool

**description:**
applied to a character argument, returns True if the character is a numeral, and False otherwise. (Import from Data.Char)

**definition:**

isDigit c = c >= '0' && c <= '9'

**usage:**

Prelude> isDigit '1'
True
Prelude> isDigit 'a'
False

isLower

**type:**

isLower :: Char -> Bool

**description:**
applied to a character argument, returns True if the character is a lower case alphabetic, and False otherwise. (Import from Data.Char)

**definition:**

isLower c = c >= 'a' && c <= 'z'

**usage:**

Prelude> isLower 'a'
True
Prelude> isLower 'A'
False
Prelude> isLower '1'
False

isSpace

**type:**

isSpace :: Char -> Bool

**description:**
returns True if its character argument is a whitespace character and False otherwise. (Import from Data.Char)

**definition:**

isSpace c = c == ' ' || c == '\t' || c == '\n' ||
c == '\r' || c == '\f' || c == '\v'

**usage:**

Prelude> dropWhile isSpace " hello 
" 
"hello \n"

10
isUpper

type: isUpper :: Char -> Bool
description: applied to a character argument, returns True if the character
is an upper case alphabetic, and False otherwise. (Import
from Data.Char)
definition: isUpper c = c >= 'A' && c <= 'Z'
usage: Prelude> isUpper 'A'
True
Prelude> isUpper 'a'
False
Prelude> isUpper '1'
False

iterate

type: iterate :: (a -> a) -> a -> [a]
description: iterate f x returns the infinite list [x, f(x), f(f(x)), ...].
definition: iterate f x = x : iterate f (f x)
usage: Prelude> iterate (+1) 1
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, ......

last

type: last :: [a] -> a
description: applied to a non–empty list, returns the last element of the list.
definition: last [x] = x
last (_:xs) = last xs
usage: Prelude> last [1..10]
10

lcm

type: lcm :: Integral a => a -> a -> a -> a
description: returns the least common multiple of its two integral argu-
ments.
definition: lcm _ 0 = 0
lcm 0 _ = 0
lcm x y = abs ((x 'quot' gcd x y) * y)
usage: Prelude> lcm 2 10
10
Prelude> lcm 2 11
22

length

type: length :: [a] -> Int
description: returns the number of elements in a finite list.
definition: length [] = 0
length (x:xs) = 1 + length xs
usage: Prelude> length [1..10]
10
lines

**type:** lines :: String -> [String]

**description:** applied to a list of characters containing newlines, returns a list of lists by breaking the original list into lines using the newline character as a delimiter. The newline characters are removed from the result.

**definition:**

```
lines [] = []
lines (x:xs) = l : ls
  where
    (l, xs') = break (== '\n') (x:xs)
    ls
      | xs' == [] = []
      | otherwise = lines (tail xs')
```

**usage:**

```
Prelude> lines "hello world\n't's me,\neric\n" 
["hello world", "it's me", "eric"]
```

log

**type:** log :: Floating a => a -> a

**description:** returns the natural logarithm of its argument.

**definition:** defined internally.

**usage:**

```
Prelude> log 1
0.0
Prelude> log 3.2
1.16315
```

map

**type:** map :: (a -> b) -> [a] -> [b]

**description:** given a function, and a list of any type, returns a list where each element is the result of applying the function to the corresponding element in the input list.

**definition:**

```
map f xs = [f x | x <- xs]
```

**usage:**

```
Prelude> map sqrt [1..5]
[1.0, 1.41421, 1.73205, 2.0, 2.23607]
```

max

**type:** max :: Ord a => a -> a -> a

**description:** applied to two values of the same type which have an ordering defined upon them, returns the maximum of the two elements according to the operator >=.

**definition:**

```
max x y
  | x >= y = x
  | otherwise = y
```

**usage:**

```
Prelude> max 1 2
2
```

12
maximum

type: maximum :: Ord a => [a] -> a

description: applied to a non-empty list whose elements have an ordering defined upon them, returns the maximum element of the list.

definition: maximum xs = foldl1 max xs

usage: Prelude> maximum [-10, 0 , 5, 22, 13]
22

min

type: min :: Ord a => a -> a -> a

description: applied to two values of the same type which have an ordering defined upon them, returns the minimum of the two elements according to the operator <=.

definition: min x y
  | x <= y = x
  | otherwise = y

usage: Prelude> min 1 2
1

minimum

type: minimum :: Ord a => [a] -> a

description: applied to a non-empty list whose elements have an ordering defined upon them, returns the minimum element of the list.

definition: minimum xs = foldl1 min xs

usage: Prelude> minimum [-10, 0 , 5, 22, 13]
-10

mod

type: mod :: Integral a => a -> a -> a

description: returns the modulus of its two arguments.

definition: defined internally.

usage: Prelude> 16 'mod' 9
7

not

type: not :: Bool -> Bool

description: returns the logical negation of its boolean argument.

definition: not True = False
   not False = True

usage: Prelude> not (3 == 4)
True
Prelude> not (10 > 2)
False
notElem

type: notElem :: Eq a => a -> [a] -> Bool
description: applied to a value and a list returns True if the value is not in the list and False otherwise. The elements of the list must be of the same type as the value.
usage: Prelude> notElem 5 [1..10]
False
Prelude> notElem "rat" ["fat", "cat", "sat", "flat"]
True

null

type: null :: [a] -> Bool
description: returns True if its argument is the empty list ([]) and False otherwise.
definition: null [] = True
null (_:_) = False
usage: Prelude> null []
True
Prelude> null (take 3 [1..10])
False

odd

type: odd :: Integral a => a -> Bool
description: applied to an integral argument, returns True if the argument is odd, and False otherwise.
definition: odd = not . even
usage: Prelude> odd 1
True
Prelude> odd (2 * 12)
False

or

type: or :: [Bool] -> Bool
description: applied to a list of boolean values, returns their logical disjunction (see also `and`).
definition: or xs = foldr (||) False xs
usage: Prelude> or [False, False, True, False]
True
Prelude> or [False, False, False, False]
False
Prelude> or []
False
ord

<table>
<thead>
<tr>
<th>type:</th>
<th>ord :: Char -&gt; Int</th>
</tr>
</thead>
<tbody>
<tr>
<td>description:</td>
<td>applied to a character, returns its ascii code as an integer. (Import from Data.Char)</td>
</tr>
<tr>
<td>definition:</td>
<td>defined internally.</td>

</table>
| usage:      | Prelude> putStr "Hello World\nI'm here!"
             | Hello World
             | I'm here! |
**product**

**type:** product :: Num a => [a] -> a

**description:** applied to a list of numbers, returns their product.

**definition:** product xs = foldl (*) 1 xs

**usage:** Prelude> product [1..10]
3628800

**quot**

**type:** quot :: Integral a => a -> a -> a

**description:** returns the quotient after dividing its first integral argument by its second integral argument.

**definition:** defined internally.

**usage:** Prelude> 16 ‘quot’ 8
2
Prelude> quot 16 9
1

**rem**

**type:** rem :: Integral a => a -> a -> a

**description:** returns the remainder after dividing its first integral argument by its second integral argument.

**definition:** defined internally.

**usage:** Prelude> 16 ‘rem’ 8
0
Prelude> rem 16 9
7

**repeat**

**type:** repeat :: a -> [a]

**description:** given a value, returns an infinite list of elements the same as the value.

**definition:** repeat x
  = xs
  where xs = x:xs

**usage:** Prelude> repeat 12
[12, 12, 12, 12, 12, 12, 12, 12, 12, 12, 12, 12, ....

16
replicate

- **type:** replicate :: Int -> a -> [a]
- **description:** given an integer (positive or zero) and a value, returns a list containing the specified number of instances of that value.
- **definition:** replicate n x = take n (repeat x)
- **usage:** Prelude> replicate 3 "apples" ["apples", "apples", "apples"]

reverse

- **type:** reverse :: [a] -> [a]
- **description:** applied to a finite list of any type, returns a list of the same elements in reverse order.
- **definition:** reverse = foldl (flip (:)) []
- **usage:** Prelude> reverse [1..10] [10, 9, 8, 7, 6, 5, 4, 3, 2, 1]

round

- **type:** round :: (RealFrac a, Integral b) => a -> b
- **description:** rounds its argument to the nearest integer.
- **usage:** Prelude> round 3.2 3
Prelude> round 3.5 4
Prelude> round (-3.2) -3

show

- **type:** show :: Show a => a -> String
- **description:** converts a value (which must be a member of the Show class), to its string representation.
- **definition:** defined internally.
- **usage:** Prelude> "six plus two equals " ++ (show (6 + 2)) "six plus two equals 8"

sin

- **type:** sin :: Floating a => a -> a
- **description:** the trigonometric sine function, arguments are interpreted to be in radians.
- **definition:** defined internally.
- **usage:** Prelude> sin (pi/2) 1.0
Prelude> ((sin pi)^2) + ((cos pi)^2) 1.0
**snd**

**type:**  
snd :: (a, b) -> b  

**description:**  
returns the second element of a two element tuple.  

**definition:**  
snd (_, y) = y  

**usage:**  
Prelude> snd ("harry", 3)  
3

**sort**

**type:**  
sort :: Ord a => [a] -> [a]  

**description:**  
sorts its argument list in ascending order. The items in the list must be in the class Ord. (Import from Data.List)  

**usage:**  
List> sort [1, 4, -2, 8, 11, 0]  
[-2,0,1,4,8,11]

**span**

**type:**  
span :: (a -> Bool) -> [a] -> ([a],[a])  

**description:**  
given a predicate and a list, splits the list into two lists (returned as a tuple) such that elements in the first list are taken from the head of the list while the predicate is satisfied, and elements in the second list are the remaining elements from the list once the predicate is not satisfied.  

**definition:**  
span p [] = ([],[])  
span p xs@(x:xs')  
| p x = (x:ys, zs)  
| otherwise = ([],xs)  
where (ys,zs) = span p xs'  

**usage:**  
Prelude> span isDigit "123abc456"  
("123", "abc456")

**splitAt**

**type:**  
splitAt :: Int -> [a] -> ([a],[a])  

**description:**  
given an integer (positive or zero) and a list, splits the list into two lists (returned as a tuple) at the position corresponding to the given integer. If the integer is greater than the length of the list, it returns a tuple containing the entire list as its first element and the empty list as its second element.  

**definition:**  
splitAt 0 xs = ([],xs)  
splitAt _ [] = ([],[])  
splitAt n (x:xs)  
| n > 0 = (x:xs',xs'')  
| otherwise = error "PreludeList.splitAt: negative argument"  
where  
(xs',xs'') = splitAt (n-1) xs  

**usage:**  
Prelude> splitAt 3 [1..10]  
([1, 2, 3], [4, 5, 6, 7, 8, 9, 10])  
Prelude> splitAt 5 "abc"  
("abc", "")
sqrt

type: \(\text{sqrt} :: \text{Floating} \; a \Rightarrow a \rightarrow a\)
description: returns the square root of a number.
definition: \(\text{sqrt} \; x = x ** 0.5\)
usage: Prelude> sqrt 16
4.0

subtract

type: \(\text{subtract} :: \text{Num} \; a \Rightarrow a \rightarrow a \rightarrow a\)
description: subtracts its first argument from its second argument.
definition: \(\text{subtract} = \text{flip} \; (-)\)
usage: Prelude> subtract 7 10
3

succ

type: \(\text{succ} :: \text{Enum} \; a \Rightarrow a \rightarrow a\)
description: applied to a value of an enumerated type returns the successor (next value in the enumeration) of its argument. If its argument is the last value in an enumeration an error will occur.
derivation: defined internally.
usage: Prelude> succ 'a'
'b'
Prelude> succ False
True

sum

type: \(\text{sum} :: \text{Num} \; a \Rightarrow [a] \rightarrow a\)
description: computes the sum of a finite list of numbers.
derivation: \(\text{sum} \; xs = \text{foldl} \; (+) \; 0 \; xs\)
usage: Prelude> sum [1..10]
55

tail

type: \(\text{tail} :: [a] \rightarrow [a]\)
description: applied to a non-empty list, returns the list without its first element.
derivation: \(\text{tail} \; (_{::}\; xs) = xs\)
usage: Prelude> tail [1,2,3]
[2,3]
Prelude> tail "hugs"
"ugs"
take

type: \( \text{take} :: \text{Int} \to [a] \to [a] \)

description: applied to an integer (positive or zero) and a list, returns the specified number of elements from the front of the list. If the list has less than the required number of elements, \( \text{take} \) returns the entire list.

definition: \[
\begin{align*}
take 0 \_ &= [] \\
take \_ [\!] &= [] \\
take \ n (x:xs) &= \begin{cases} x : \text{take} \ (n-1) \ xs & | n > 0 \\ \text{take} \_ \_ &= \text{error} \ "\text{PreludeList.take: negative argument}\" \\
\end{cases}
\end{align*}
\]

usage:
Prelude> take 4 "goodbye"
"good"
Prelude> take 10 [1,2,3]
[1,2,3]

takeWhile

type: \( \text{takeWhile} :: (a \to \text{Bool}) \to [a] \to [a] \)

description: applied to a predicate and a list, returns a list containing elements from the front of the list while the predicate is satisfied.

definition: \[
\begin{align*}
\text{takeWhile} \ p \ [\!] &= [\!
\text{takeWhile} \ p (x:xs) &= \begin{cases} x : \text{takeWhile} \ p xs & | p \ x \\
\text{otherwise} &= []
\end{cases}
\end{align*}
\]

usage:
Prelude> takeWhile (<5) [1, 2, 3, 10, 4, 2]
[1, 2, 3]

tan

type: \( \text{tan} :: \text{Floating} \ a \Rightarrow a \to a \)

description: the trigonometric function \( \tan \), arguments are interpreted to be in radians.

definition: defined internally.

usage:
Prelude> tan (pi/4)
1.0
toLower

type: \[\text{toLower} :: \text{Char} \to \text{Char}\]
description: converts an uppercase alphabetic character to a lowercase alphabetic character. If this function is applied to an argument which is not uppercase the result will be the same as the argument unchanged. (Import from \textit{Data.Char})
definition: \[
\text{toLower} c \\
| \text{isUpper} c = \text{toEnum} (\text{fromEnum} c - \text{fromEnum} 'A' + \text{fromEnum} 'a') \\
| \text{otherwise} = c
\]
usage: Prelude\> \text{toLower} 'A' \\
'\text{a}' \textstyle\> \text{toLower} '3' \\
'3'

toUpper

type: \[\text{toUpper} :: \text{Char} \to \text{Char}\]
description: converts a lowercase alphabetic character to an uppercase alphabetic character. If this function is applied to an argument which is not lowercase the result will be the same as the argument unchanged. (Import from \textit{Data.Char})
definition: \[
\text{toUpper} c \\
| \text{isLower} c = \text{toEnum} (\text{fromEnum} c - \text{fromEnum} 'a' + \text{fromEnum} 'A') \\
| \text{otherwise} = c
\]
usage: Prelude\> \text{toUpper} 'a' \\
'A' \textstyle\> \text{toUpper} '3' \\
'3'

truncate

type: \[\text{truncate} :: (\text{RealFrac} a, \text{Integral} b) \Rightarrow a \to b\]
description: drops the fractional part of a floating point number, returning only the integral part.
usage: Prelude\> \text{truncate} 3.2 \\
3 \textstyle\> \text{truncate} (-3.2) \\
-3

undefined

type: \[\text{undefined} :: a\]
description: an undefined value. It is a member of every type.
definition: \[
\text{undefined} \\
| \text{False} = \text{undefined}
\]
unlines

 type:         unlines :: [String] -> String

description:  converts a list of strings into a single string, placing a new-
              line character between each of them. It is the converse of the
              function lines.

definition:   unlines xs
              = concat (map addNewLine xs)
              where
              addNewLine l = l ++ "\n"

usage:        Prelude> unlines ["hello world", "it's me","eric"]
              "hello world\nit's me,\neric\n"

until

 type:         until :: (a -> Bool) -> (a -> a) -> a -> a

description:  given a predicate, a unary function and a value, it recursively
              re–applies the function to the value until the predicate is satis-
              fied. If the predicate is never satisfied until will not terminate.

definition:   until p f x
              | p x = x
              | otherwise = until p f (f x)

usage:        Prelude> until (>1000) (*2) 1
              1024

unwords

 type:         unwords :: [String] -> String

description:  concatenates a list of strings into a single string, placing a single
              space between each of them.

definition:   unwords [] = []
unwords ws
              = foldr1 addSpace ws
              where
              addSpace w s = w ++ (' ':s)

usage:        Prelude> unwords ["the", "quick", "brown", "fox"]
              "the quick brown fox"
words

type: \[\text{words : String} \rightarrow [\text{String}]\]
description: breaks its argument string into a list of words such that each word is delimited by one or more whitespace characters.
definition: \[\text{words } s\]
\[| \text{findSpace} == [] = []\]
\[| \text{otherwise} = w : \text{words } s''\]
where
\[(w, s'') = \text{break isSpace findSpace}\]
\[\text{findSpace} = \text{dropWhile isSpace } s\]
usage: Prelude> \text{words } "\text{the quick brown\n\nfox}"
["\text{the}", "\text{quick}", "\text{brown}", "\text{fox}\"]

zip

type: \[\text{zip : [a]} \rightarrow [b] \rightarrow [(a,b)]\]
description: applied to two lists, returns a list of pairs which are formed by tupling together corresponding elements of the given lists. If the two lists are of different length, the length of the resulting list is that of the shortest.
definition: \[\text{zip } xs\]
\[\text{ys} = \text{zipWith pair } xs\]
\[\text{ys}\]
where
\[\text{pair } x\ y = (x, y)\]
usage: Prelude> \text{zip } [1..6] "abcd"
[(1, 'a'), (2, 'b'), (3, 'c'), (4, 'd')]

zipWith

type: \[\text{zipWith : (a} \rightarrow (b} \rightarrow (c)) \rightarrow [a] \rightarrow [b] \rightarrow [c]\]
description: applied to a binary function and two lists, returns a list containing elements formed by applying the function to corresponding elements in the lists.
definition: \[\text{zipWith } z (a:a:s) (b:b:s) = z a\ b : \text{zipWith } z\ a\ s\]
\[\text{zipWith } _\_\_ = []\]
usage: Prelude> \text{zipWith } (+) [1..5] [6..10]
[7, 9, 11, 13, 15]
1.2 A description of standard Haskell operators

Operators are simply functions of one or two arguments. Operators usually get written between their arguments (called infix notation), rather than to the left of them. Many operators have symbolic names (like + for plus), however this is out of convention rather than necessity. Others have completely textual names (such as ‘div’ for integer division).

The following table lists many useful operators defined in the Prelude. Definitions of associativity and binding power are given after the table.

<table>
<thead>
<tr>
<th>symbol</th>
<th>behaviour</th>
<th>type</th>
<th>associativity</th>
<th>binding power</th>
</tr>
</thead>
<tbody>
<tr>
<td>!!</td>

</tr>
</tbody>
</table>

The higher the binding power the more tightly the operator binds to its arguments.

Function application has a binding power of 10, and so takes preference over any other operator application.
**Associativity:** sequences of operator applications are allowed in Haskell for the convenience of the programmer. However, in some circumstances the meaning of such a sequence can be ambiguous. For example, we could interpret the expression $8 - 2 - 1$ in two ways, either as $(8 - 2) - 1$, or as $8 - (2 - 1)$ (each interpretation having a different value). Associativity tells us whether a sequence of a particular operator should be bracketed to the left or to the right. As it happens, the minus operator ($-$) is left associative, and so Haskell chooses the first of the alternative interpretations as the meaning of the above expression. The choice of associativity for an operator is quite arbitrary, however, they usually follow conventional mathematical notation. Note that some operators are non-associative, which means that they cannot be applied in sequence. For example, the equality operator ($==$) is non-associative, and therefore the following expression is not allowed in Haskell: $2 == (1 + 1) == (3 - 1)$.

**Binding Power:** Haskell expressions may also contain a mixture of operator applications which can lead to ambiguities that the rules of associativity cannot solve. For example, we could interpret the expression $3 - 4 * 2$ in two ways, either as $(3 - 4) * 2$, or as $3 - (4 * 2)$ (each interpretation having a different value). Binding power tells us which operators take precedence in an expression containing a mixture of operators. The multiplication operator ($*$), has a binding power of 7 (out of a possible 10), and the minus operator ($-$) has a binding power of 6. Therefore the multiplication operator takes precedence over the minus operator, and thus Haskell chooses the second of the alternative interpretations as the meaning of the above expression. All operators must have a binding power assigned to them which ranges from 1 to 10. Function application takes precedence over everything else in an expression, and so the expression `reverse [1..10] ++ [0]` is interpreted as `(reverse [1..10]) ++ [0]`, rather than `reverse ([1..10] ++ [0])`.

### 1.3 Using the standard Haskell operators

(!)  
**description:** given a list and a number, returns the element of the list whose position is the same as the number.  
**usage:**  
```
Prelude> [1..10] !! 0
1
Prelude> "a string" !! 3
't'
```  
**notes:** the valid subscripts for a list l are: $0 \leq \text{subscript} \leq ((\text{length } l) - 1)$. Therefore, negative subscripts are not allowed, nor are subscripts greater than one less than the length of the list argument. Subscripts out of this range will result in a program error.

(.  
**description:** composes two functions into a single function.  
**usage:**  
```
Prelude> (sqrt . sum) [1,2,3,4,5]
3.87298
```  
**notes:** $(f \cdot g \cdot h) x$ is equivalent to $f (g (h x))$.  

(**)

description: raises its first argument to the power of its second argument.
The arguments must be in the Floating numerical type class, and the result will also be in that class.

usage: Prelude> 3.2**pi
38.6345

(\-)

description: raises its first argument to the power of its second argument.
The first argument must be a member of the Num typeclass, and the second argument must be a member of the Integral typeclass. The result will be of the same type as the first argument.

usage: Prelude> 3.2^-4
104.858

(\-\-)

description: raises its first argument to the power of its second argument.
The first argument must be a member of the Fractional typeclass, and the second argument must be a member of the Integral typeclass. The result will be of the same type as the first argument.

usage: Prelude> 3.142^-4
97.4596

(%)

description: takes two numbers in the Integral typeclass and returns the most simple ratio of the two.

usage: Prelude> 20 % 4
5 % 1
Prelude> (5 % 4)^2
25 % 16

(*)

description: returns the multiple of its two arguments.

usage: Prelude> 6 * 2.0
12.0

(/)

description: returns the result of dividing its first argument by its second.
Both arguments must in the type class Fractional.

usage: Prelude> 12.0 / 2
6.0
(+)

**description:** returns the addition of its arguments.

**usage:**

```haskell
Prelude> 3 + 4
7
Prelude> (4 % 5) + (1 % 5)
1 % 1
```

(−)

**description:** returns the subtraction of its second argument from its first.

**usage:**

```haskell
Prelude> 4 - 3
1
Prelude> 4 - (-3)
7
```

(:)

**description:** prefixes an element onto the front of a list.

**usage:**

```haskell
Prelude> 1:[2,3]
[1,2,3]
Prelude> True:[]
[True]
Prelude> 'h':"askell"
"askell"
```

(++)

**description:** appends its second list argument onto the end of its first list argument.

**usage:**

```haskell
Prelude> [1,2,3] ++ [4,5,6]
[1,2,3,4,5,6]
Prelude> "foo " ++ "was" ++ " here"
"foo was here"
```

(/=)

**description:** is True if its first argument is not equal to its second argument, and False otherwise. Equality is defined by the == operator. Both of its arguments must be in the Eq type class.

**usage:**

```haskell
Prelude> 3 /= 4
True
Prelude> [1,2,3] /= [1,2,3]
False
```

(==)

**description:** is True if its first argument is equal to its second argument, and False otherwise. Equality is defined by the == operator. Both of its arguments must be in the Eq type class.

**usage:**

```haskell
Prelude> 3 == 4
False
Prelude> [1,2,3] == [1,2,3]
True
```
(<)

description: returns True if its first argument is strictly less than its second argument, and False otherwise. Both arguments must be in the type class Ord.

usage:

Prelude> 1 < 2
True
Prelude> 'a' < 'z'
True
Prelude> True < False
False

(<=)

description: returns True if its first argument is less than or equal to its second argument, and False otherwise. Both arguments must be in the type class Ord.

usage:

Prelude> 3 <= 4
True
Prelude> 4 <= 4
True
Prelude> 5 <= 4
False

(>)

description: returns True if its first argument is strictly greater than its second argument, and False otherwise. Both arguments must be in the type class Ord.

usage:

Prelude> 2 > 1
True
Prelude> 'a' > 'z'
False
Prelude> True > False
True

(>=)

description: returns True if its first argument is greater than or equal to its second argument, and False otherwise. Both arguments must be in the type class Ord.

usage:

Prelude> 4 >= 3
True
Prelude> 4 >= 4
True
Prelude> 4 >= 5
False
(&&)

description: returns the logical conjunction of its two boolean arguments.

usage:
Prelude> True && True
True
Prelude> (3 < 4) && (4 < 5) && False
False

(||)

description: returns the logical disjunction of its two boolean arguments.

usage:
Prelude> True || False
True
Prelude> (3 < 4) || (4 > 5) || False
True
1.4 Type Classes from the Haskell Prelude

Eq

description: Types which are instances of this class have equality defined upon them. This means that all elements of such types can be compared for equality.

instances: • All Prelude types except IO and functions.

notes: Functions which use the equality operators (==, /=) or the functions elem or notElem will often be subject to the Eq type class, thus requiring the constraint Eq a => in the type signature for that function.

Ord

description: Types which are instances of this class have a complete ordering defined upon them.

instances: • All Prelude types except IO, functions, and I0Error.

notes: Functions which use the comparison operators (> , < , >=, <=), or the functions max, min, maximum or minimum will often be subject to the Ord type class, thus requiring the constraint Ord a => in the type signature for that function.

Enum

description: Types which are instances of this class can be enumerated. This means that all elements of such types have a mapping to a unique integer, thus the elements of the type must be sequentially ordered.

instances: • Bool
• Char
• Int
• Integer
• Float
• Double

notes: Functions which use dot-dot notation (eg [1,3 .. y]) in list comprehensions will often be subject to the Enum type class, thus requiring the constraint Enum a => in the type signature for that function.

Show

description: Types which are instances of this class have a printable representation. This means that all elements of such types can be given as arguments to the function show.

instances: • All Prelude types.

notes: Functions which use the function show will often be subject to the Show type class, thus requiring the constraint Show a => in the type signature for that function.
Read

description: Types which are instances of this class allow a string representation of all elements of the type to be converted to the corresponding element.

instances: • All Prelude types except IO and functions.

notes: Functions which use the function read will often be subject to the Read type class, thus requiring the constraint Read a => in the type signature for that function.

Num

description: This is the parent class for all the numeric classes. Any type which is an instance of this class must have basic numeric operators (such as plus, minus and multiply) defined on them, and must be able to be converted from an Int or Integer to an element of the type.

instances:
  • Int
  • Integer
  • Float
  • Double

notes: Functions which perform operations which are applicable to all numeric types, but not to other non–numeric types will often be subject to the Num type class, thus requiring the constraint Num a => in the type signature for that function.

Real

description: This class covers all the numeric types whose elements can be expressed as a ratio.

instances:
  • Int
  • Integer
  • Float
  • Double

Fractional

description: This class covers all the numeric types whose elements are fractional. All such types must have division defined upon them, they must have a reciprocal, and must be convertible from rational numbers, and double precision floating point numbers.

instances:
  • Float
  • Double

notes: Functions which use the division operator (/) will often be subject to the Fractional type class, thus requiring the constraint Fractional a => in the type signature for that function.

Integral

description: This class covers all the numeric types whose elements are integral.
instances:  
  • Int  
  • Integer

notes:  
Functions which use the operators `div` or `mod` will often be subject to the `Integral` type class, thus requiring the constraint `Integral a =>` in the type signature for that function.

**Floating**

description:  
This class covers all the numeric types whose elements are floating point numbers.

instances:  
  • Float  
  • Double

notes:  
Functions which use the constant `pi` or the functions `exp`, `log`, `sqrt`, `sin`, `cos` or `tan` will often be subject to the `Floating` type class, thus requiring the constraint `Floating a =>` in the type signature for that function.

1.5 The Haskell Prelude Class hierarchy

```
   Eq  
  ↘   ↘  
 Ord Show  
  ↘   ↘  
 Enum Real Fractional  
  ↘   ↘  
 Integral Floating
```

**Read**

Figure 1: A sample of the class hierarchy from the Haskell Prelude

Figure 1 illustrates a sample of the type class hierarchy from the Haskell Prelude. Arrows in the diagram represent the ordering of classes in the hierarchy. For example, for a type to be in the class `Ord` it must also be in the class `Eq`. Note that the class `Read` is separate from the rest of the hierarchy.
